MRF FORECAST ARCHIVE

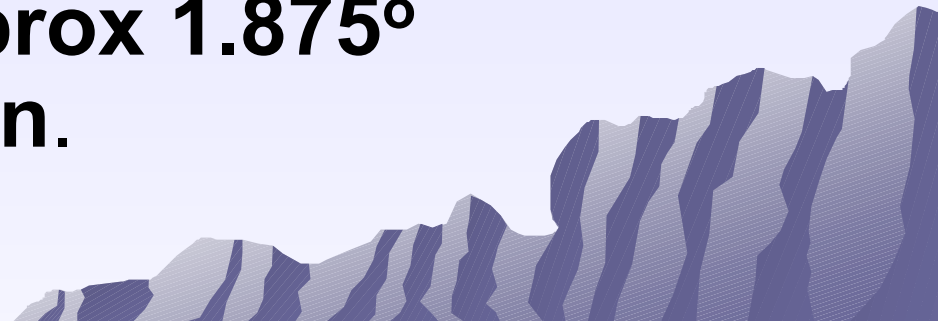

- ❑ **The NCEP/NCAR reanalysis –**

a 40+ year record of global atmospheric fields and surface fluxes derived from a numerical weather prediction and data assimilation system kept unchanged over the analysis period

- ❑ **Every five days, a single realization of an 8-day forecast was run**

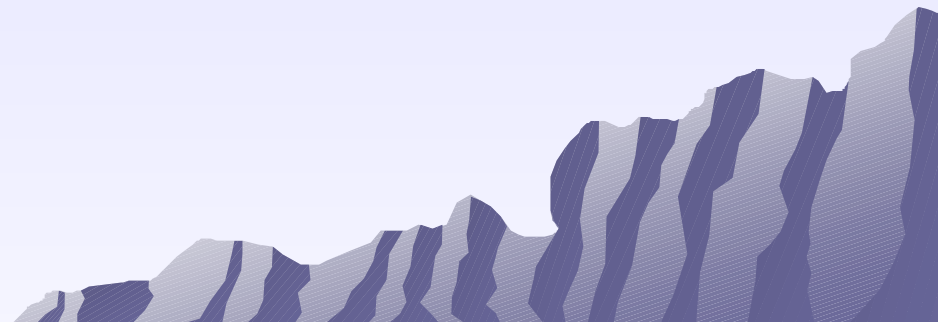

for the period 1958-1998, this provides over 2500 8-day forecasts that can be compared with observations

- ❑ **Model output is archived on a regular lat/lon grid with approx 1.875° horizontal resolution.**

Clear need for additional post-processing of NCEP output before it can be used in hydrologic applications

DAY 8

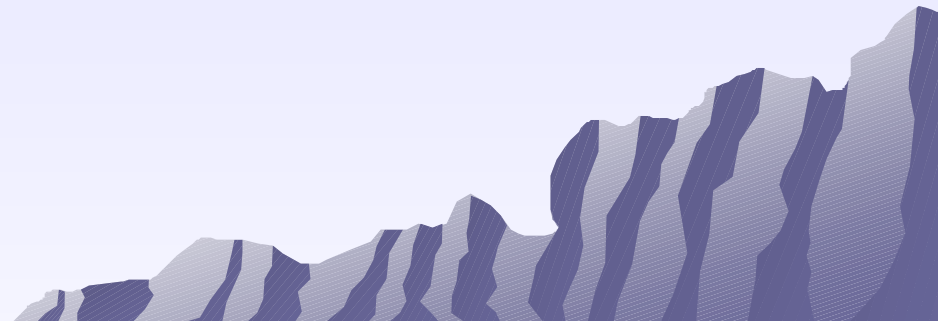

THE CDC-SCRIPPS RE-FORECAST EXPERIMENT

- ❑ Uses a fixed version (circa 1998) of the NCEP operational MRF.
 - ❑ Ultimate goal – to generate an ensemble of eleven 21-day forecasts for the past 23 years (1978-2001), initialized with boundary conditions from the reanalysis project
 - ❑ **Control run already completed.**
-

Generate an archive of atmospheric forecasts

**Develop downscaling relationships, and apply to the
operational forecast model**

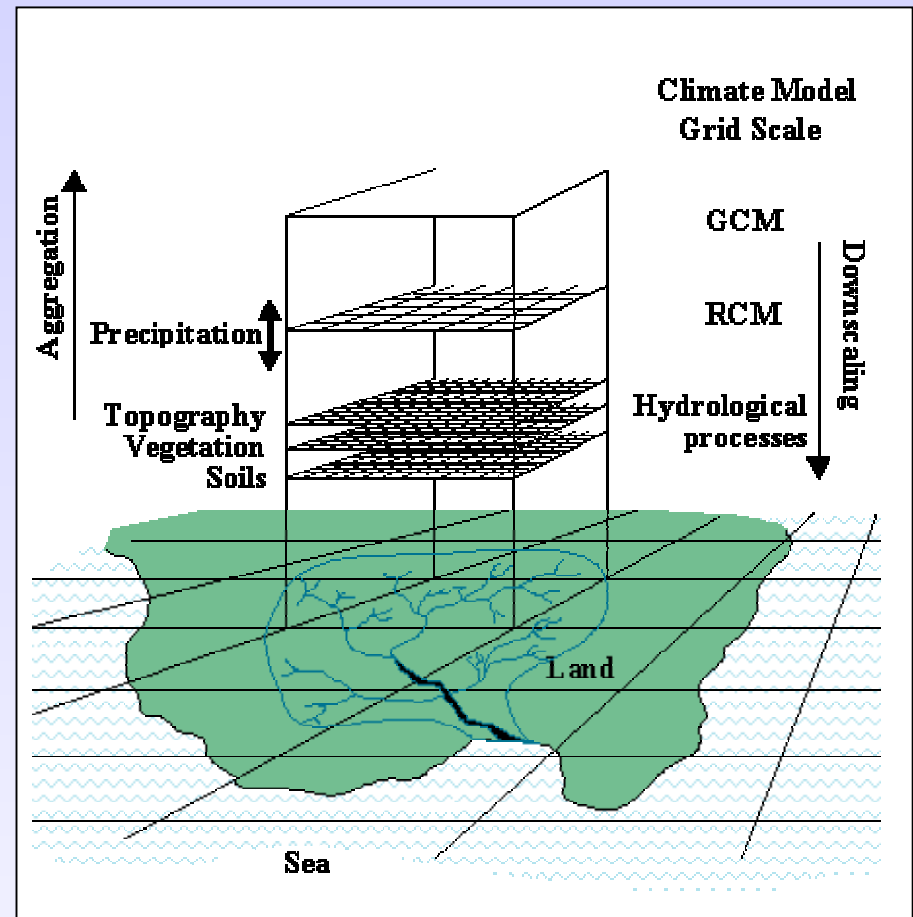

DOWNSCALING OF THE NCEP MRF OUTPUT

- ❑ **Use Multiple linear Regression with forward selection**
- ❑ **Predictor Variables (over 300):**
 - Geo-potential height, wind, and humidity at five pressure levels
 - Various surface flux variables
 - Computed variables such as vorticity advection, stability indices, etc.
 - Variables lagged to account for temporal phase errors in atmospheric forecasts.
- ❑ **Predictands are maximum and minimum temperature, precipitation occurrence, and precipitation amounts**

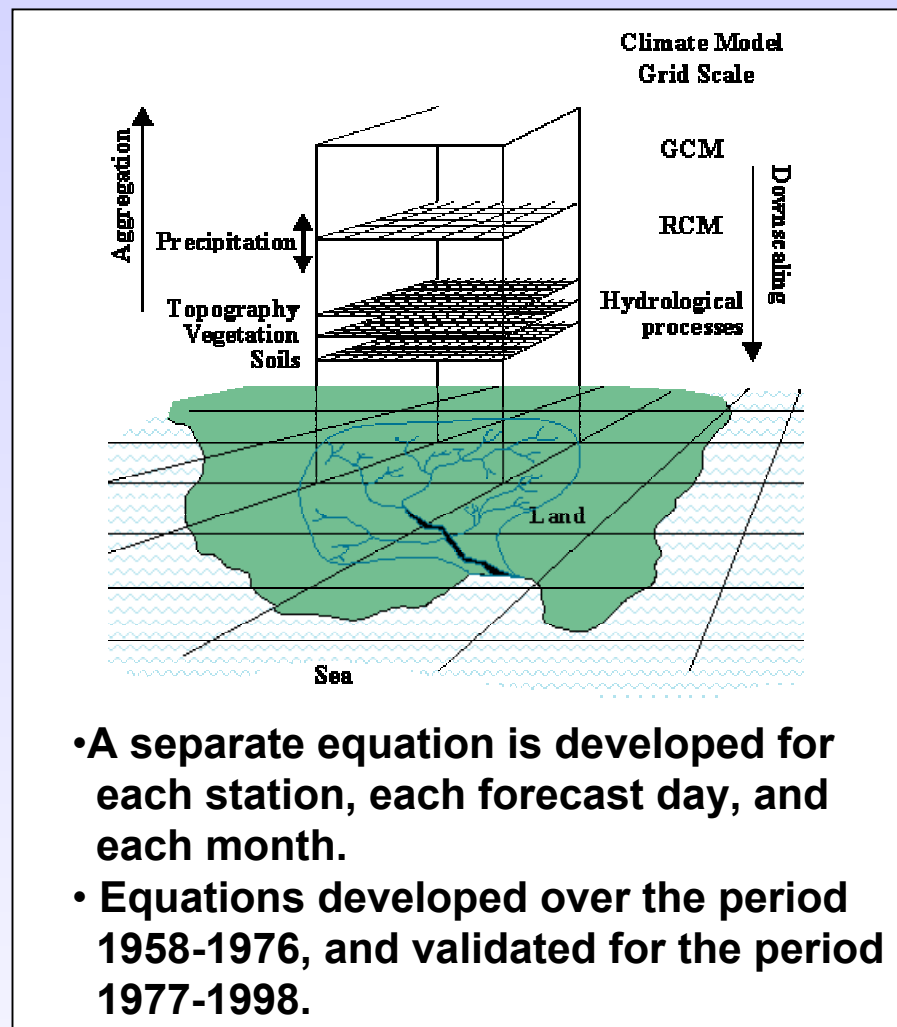

DOWNSCALING OF THE NCEP MRF OUTPUT

- ❑ **Use Multiple linear Regression with forward selection**
- ❑ **Predictor Variables (over 300):**
 - Geo-potential height, wind, and humidity at five pressure levels
 - Various surface flux variables
 - Computed variables such as vorticity advection, stability indices, etc.
 - Variables lagged to account for temporal phase errors in atmospheric forecasts.
- ❑ **Predictands are maximum and minimum temperature, precipitation occurrence, and precipitation amounts**
- ❑ **Use cross-validation procedures for variable selection – typically less than 8 variables are selected for a given equation**
- ❑ **Stochastic modeling of the residuals in the regression equation to provide ensemble time series**

INTRASEASONAL HYDROLOGIC FORECASTS

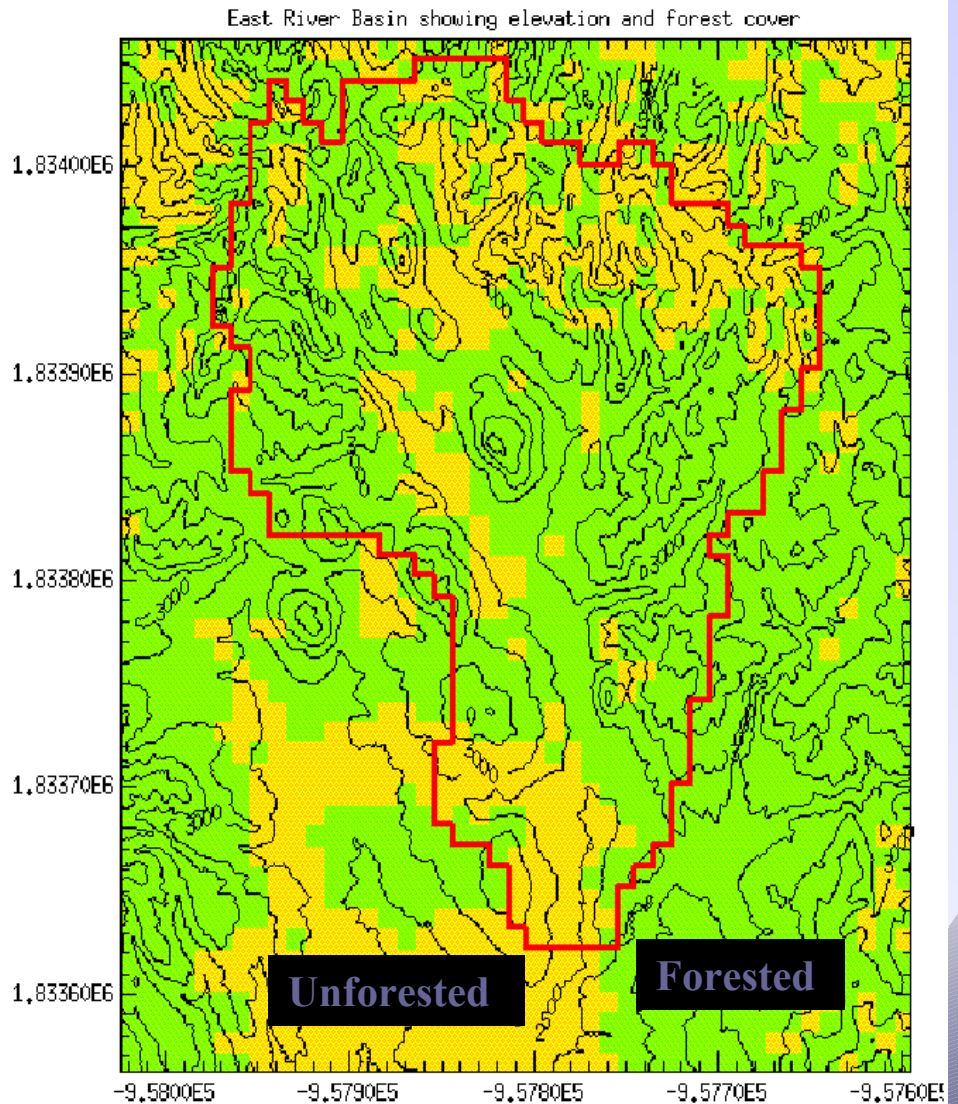

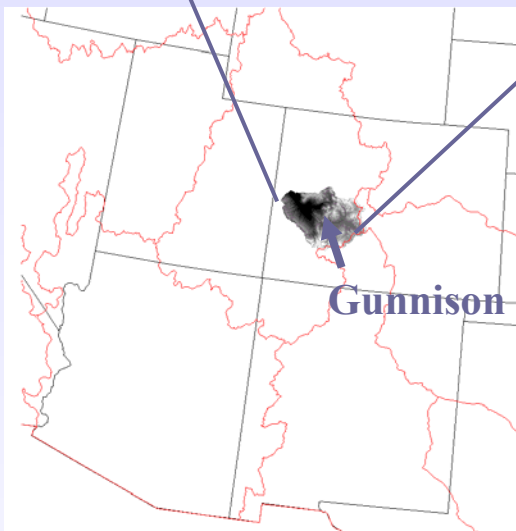

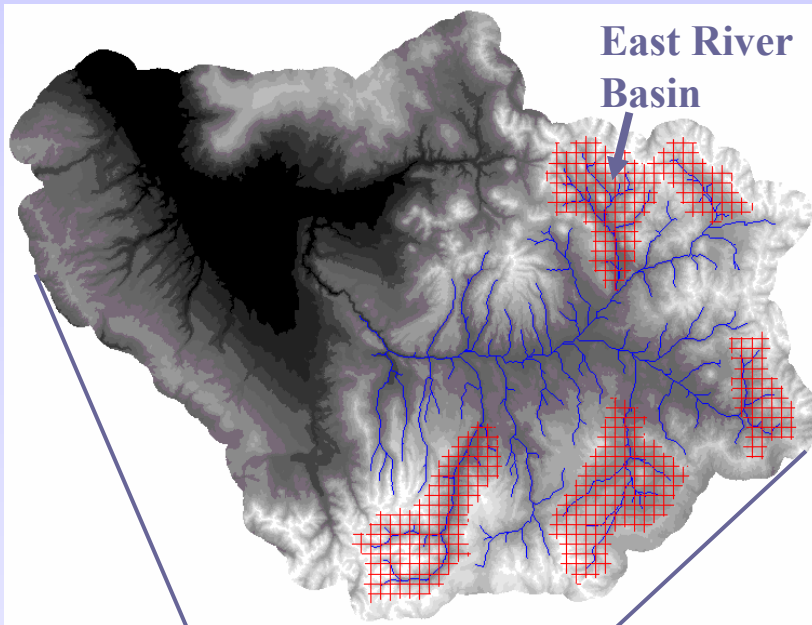

Generate an archive of atmospheric forecasts

Develop downscaling relationships, and apply to the operational forecast model

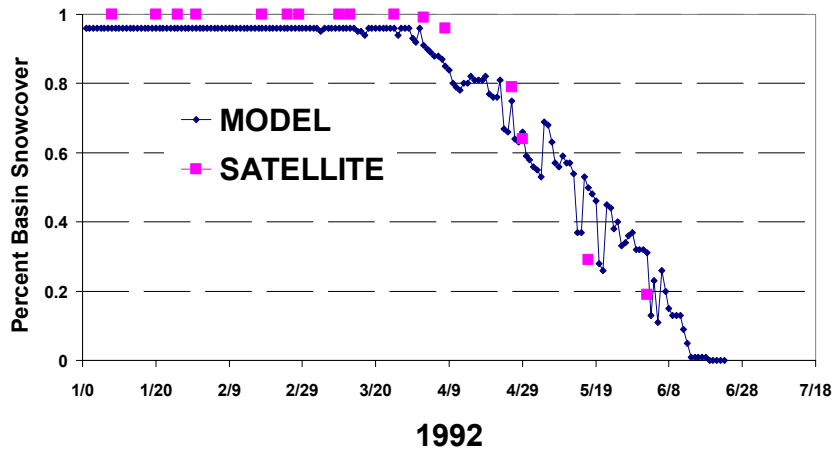

Estimate basin initial conditions

Run hydrologic models in ensemble mode to provide probabilistic forecasts of streamflow and estimates of forecast uncertainty

MULTI-MODEL SUPER-ENSEMBLES IN HYDROLOGY

Two Hypotheses:

- ❑ The mean of runoff simulations from multiple models will be superior to the runoff simulation from any given model
 - ❑ The spread of the hydrologic model ensemble is related to the error in the hydrologic simulation
- 
- A decorative graphic of a mountain range in shades of blue and purple, located in the bottom right corner of the slide.

SUMMARY AND OUTLOOK

- ❑ The large biases in output from medium range forecast models creates a need for post-processing of model output in order for it to be effectively used in hydrologic simulations.
- ❑ Our downscaling system is successful in both removing mean model biases, and improving the skill in the raw NCEP output.
- ❑ When the downscaled NCEP output is used as input to hydrologic models, forecasts of runoff have greater skill than the forecasts generated with the traditional ESP approach.
